

1. SKLEARN.MODEL_SELECTION

```
from sklearn.model_selection import train_test_split
```

First of all, the `sklearn.model_selection` is a module that provides functions for splitting into training and test sets, evaluating machine learning models, and performing validation

In any machine learning model datasets, we divide them into 2 types of data, one is only for testing and one is only for training with the normally 80/20 ratio.

The 80/training data will be used to train the model and the 20/test data will be used to test the model, which will use certain mathematical functions to assess the accuracy of the model.

Way to execute this:

```
x_train, x_test, y_train, y_test = train_test_split(x, y,  
test_size=0.3, random_state=42)
```

2. SKLEARN.PREPROCESSING

```
from sklearn.preprocessing import PolynomialFeatures, StandardScaler,  
StandardScaler, MinMaxScaler, LabelEncoder, OneHotEncoder, Inputer
```

The `sklearn.preprocessing` model is a module that provides certain methods to alter the value of the whole datasets. This module offers a wide array of tools for data processing, which explains preprocessing-modules to process after training and testing.

These methods include techniques for scaling, encoding, transforming, and inputting data.

For Linear Regression
